

Profiling Tools for Performance Metrics

Theodoros Theodoris
Feb. 2024

Eidgenössische Technische Hochschule Zürich
Swiss Federal Institute of Technology Zurich

Performance Monitoring

Modern CPUs can measure various performance related parameters:

Raw metrics: e.g., number of vectorized instructions

Performance events: e.g., number of cycles “wasted” waiting for memory

Branch recording: tracking which branches (“if statements, loops) are executed and how many times

...

Performance Counters

Performance counters are special registers that can be configured to track the event of interest, e.g.:

- *# scalar executed floating point operations.*
- *# vectorized executed floating point operations.*
- *# branch misses*
- *# cache misses*

For more details on performance counters look at the performance counters slides on the course website

Profiling Tools

Profiling tools help with measuring and identifying performance related events and metrics

This is typically done by running the target program and sampling the relevant CPU's performance counters

Metrics can be counted throughout a program's execution (e.g., total number of memory transactions), or correlated with certain program locations (i.e., finding hotspots)

Hierarchical analyses, such as, the [Top-down Microarchitecture Analysis Method](#) (TMA), can be used to systematically identify bottlenecks

(non-exhaustive) List of Profiling Tools

[Intel VTune](#) is probably the most feature complete tool

[AMD uProf](#) supports AMD specific events

[Apple Xcode Instruments](#) can access perf. counters on M1 and M2 CPUs

[Linux perf](#) is a command line that can measure most things that VTune can, but it is less intuitive and without a GUI

[toplev](#) implements [Top-down Microarchitecture Analysis Method](#) (only works on Intel+Linux based systems)

perf-book

The [perf-book](#) is a great resource that demonstrates (lots of examples) various tools and methodologies for performance analysis. Some interesting chapters:

Performance Analysis Approaches (5) show various methods that enable performance, instrumentation, sampling, compiler optimization reports, etc.

CPU Features for Perf. Analysis (6) explains mechanisms implemented in CPUs that facilitate performance analysis

Overview of Tools (7) is a quick tour of various tools such as Vtune

Perf Example: counting events (1/2)

Given a program a.out, we can ask perf to count performance related metrics:

```
perf stat ./a.out
Performance counter stats for './a.out':
    0.79 msec task-clock:u          #    0.751 CPUs utilized
         0      context-switches:u   #    0.000 /sec
         0      cpu-migrations:u     #    0.000 /sec
         79     page-faults:u        #   99.912 K/sec
  2,052,295    cycles:u              #    2.596 GHz
  2,403,057    instructions:u        #    1.17  insn per cycle
   511,384     branches:u           #   646.750 M/sec
     5,022     branch-misses:u      #    0.98% of all branches
 10,261,475    slots:u              #   12.978 G/sec
   2,736,393   topdown-retiring:u    #   26.7% retiring
   482,892     topdown-bad-spec:u    #    4.7% bad speculation
   965,785     topdown-fe-bound:u    #    9.4% frontend bound
  6,076,402   topdown-be-bound:u    #   59.2% backend bound
```

Around 1% of the
branches were
mispredicted

Perf Example: counting events (2/2)

To measure a specific metric:

```
perf stat -e LLC-load-misses ./a.out
Performance counter stats for './a.out':

      291      LLC-load-misses:u
```

The exact name event (metric) name depends on the CPU. `perf list` shows the supported events.

Multiple events can be measured:

```
perf stat -e fp_arith_inst_retired.256b_packed_single,LLC-load-misses ./a.out
Performance counter stats for './a.out':

    240,000      fp_arith_inst_retired.256b_packed_single:u
       285      LLC-load-misses:u
```

240,000 vectorized arithmetic instructions were executed

Perf: sampling

The previous examples showed how to count specific events (e.g., number of cache misses).

perf can also use sampling to identify which parts of a program trigger those events (perf record).

[Linux perf Examples \(brendangregg.com\)](http://brendangregg.com) shows various examples.
